Input and Output Exercise

Develop a simple university application that receives a student name, asks for age and course information, saves it to a text file, and reads it back.

Tasks

1. Read Command-Line Arguments

- Create a C# Console Application using Main(string[] args).
- Read the first argument as the student name. If no argument is provided, use "Unknown".
- Display the name using Console.WriteLine().

2. Read and Parse User Input

- Ask for the student's age using Console.ReadLine() and convert it with int.Parse().
- Ask for the course and grade in the format OOP,12.
- Use Split(',') to separate the values and int.Parse() to convert the grade.

3. Write Information to a File

- Create student.txt using StreamWriter.
- Write the student name, age, course, and grade on separate lines.
- Close the writer after saving.

4. Read Information from the File

- Check whether student.txt exists using File.Exists().
- If it exists, use StreamReader to read the file and display its contents.
- Close the reader after reading.

Starter Code

```
using System;
using System.IO;

public class Program
{
    public static void Main(string[] args)
    {
        // TODO 1: Read student name from args (or use Unknown)
        // TODO 2: Read age and convert using int.Parse()
        // TODO 3: Read course and grade, use Split(',')
        // TODO 4: Write information using StreamWriter
        // TODO 5: Check file with File.Exists()
        // TODO 6: Read and display using StreamReader
    }
}
```

Expected Output

Run: dotnet run -- Peter

```
Student: Peter
Enter age: 20
Enter course and grade: OOP,12

Information saved successfully!
Reading student.txt:
Name: Peter
```

Age: 20
Course: OOP
Grade: 12
