Exercise Paramterized Type

A shop needs a program to store information about different products. Each product has two pieces of information, such as a product name and a price, or a product ID and a category. Instead of creating separate classes for every combination of data types, create one Generic class that works with different types.

Part 1 — Create a Generic Class

Create a class called ProductInfo<T1, T2>. Your class must:

1. Have two public properties: First of type T1 and Second of type T2.
2. Have a constructor that initializes both properties.
3. Have a method SetFirst(T1 value) that updates the first property.
4. Have a method SetSecond(T2 value) that updates the second property.
5. Override ToString() to display both values.

Part 2 — Use the Generic Class

6. Create a ProductInfo<string, double> object containing "Laptop" and 850.5.
7. Create a ProductInfo<int, string> object containing 101 and "Electronics".
8. Print both objects using Console.WriteLine().
9. Use SetSecond() to change the laptop price to 799.9.
10. Print the updated laptop information.

Starter Code

```
using System;

namespace GenericExercise
{
    class ProductInfo<T1, T2>
    {
        // TODO: Create two properties
        // TODO: Create a constructor
        // TODO: Create SetFirst() and SetSecond()
        // TODO: Override ToString()
    }

    class Program
    {
        static void Main(string[] args)
        {
            // TODO: Create products with different types
            // TODO: Print both products
            // TODO: Update the laptop price
            // TODO: Print the updated product
        }
```

```
    }
}
```

Expected Output

Laptop, 850.5
101, Electronics
Laptop, 799.9
Note: Decimal formatting may vary with regional settings.
