Student Information System

Create a C# Console App with a Student class and a Program class. The program must keep track of student information without allowing other classes to change private fields directly.

1. Declare private instance fields name (string) and age (int).
2. Create a constructor Student(string name, int age). Use this to distinguish fields from parameters.
3. Implement GetName(), GetAge(), and SetAge(int age). Reject negative ages with an ArgumentException.
4. Add a private static field studentCount, increment it in the constructor, and expose public static GetStudentCount().
5. In Main, create Peter (20) and Mads (22), print their names and ages, update Peter's age to 21, and print the student count.
6. Write one commented-out statement that would fail because it accesses a private field from Program.

Starter structure

```
using System;

public class Student
{
    // TODO: fields, constructor, getters, setter, static counter
}

public class Program
{
    public static void Main(string[] args)
    {
        // TODO: create objects and test the methods
    }
}
```

Think about:

Why is studentCount static?

Why should SetAge validate the input?

What does this.age mean?
